Appendix 1. Genetic Results for Fish Captured in Mess Lake

1. Introduction

1. Introduction

The Schaft Creek Project Fisheries Baseline 2008 was produced in February 2010 and contained the results from genetic analyses of unidentified salmonids captured in Mess Lake. The unidentified salmonids were positively identified as *Oncorhynchus nerka*, or Kokanee salmon, a freshwater form of sockeye salmon. While the results from these analyses were reported in the baseline report, the supporting lab results were not included in the appendices. This addendum presents a review of the methods used to genetically identify the specimens from Mess Lake, as well as the original lab results. The lab results are presented in the attached appendix.

2. Methods

2. Methods

Genetic samples were sent to Dr. Eric Taylor at the University of British Columbia Department of Zoology for identification. DNA was extracted from ethanol-stored fin tissues using standard spin column protocols (Qiagen Ltd). The DNA of each fish was subject to polymerase chain reaction (PCR) amplification and sequencing of the cytochrome oxidase I (CO1) gene of the mitochondrial DNA genome. This gene is the standard used for fishes for molecular identification using "DNA bar-coding". Resultant sequences (about 853 base pairs) were submitted to the Barcode of Life Database (BOLD) (Hubert *et al.* 2008, Ratnasingham and Hebert 2007) to identify the DNA samples to species.

Genetic Results for Fish Captured in Mess Lake

DNA Species Identification Report

Eric Taylor

UBC Zoology
etaylor@zoology.ubc.ca

October 2, 2008

Locality: Mess Lake (tributary of Stikine River, in Mt. Edziza Park)

Number of samples: 24

Date: Assayed September, 2008

Methods: DNA was extracted from ethanol-stored fin tissues using standard “spin-column” protocols (Qiagen Ltd). Each fish’s DNA was subject to polymerase chain reaction (PCR) amplification and sequencing of the cytochrome oxidase I (CO1) gene of the mitochondrial DNA genome. This gene is the standard used for fishes for molecular identification using “DNA barcoding”. Resultant sequences (about 853 base pairs) were submitted to the Barcode of Life Database (BOLD, see <http://www.boldsystems.org/views/login.php>) to identify the DNA samples to species.

General results (see attached spreadsheet for details).

All fish except five were successfully assayed and all of these fish were positively identified (> 99% sequence similarity) as *Oncorhynchus nerka*. An example of specimen similarity to *O. nerka* can be seen in the attached phylogenetic tree (“final-tree 4-4) based on the sequence submitted (specimen July 4, No. 4)) to the BOLD database.

The five specimens (5-12, 5-14, 5-16, 5-18, 5-22) that could not be assayed (despite several attempts) appeared to have had their tissues stored in clove oil rather than ethanol. Upon opening the tubes containing these tissue samples, there was an unmistakable and strong odour of cloves. The storage medium was also a golden-yellow colour.
